What type of environmental assessment and modification prevents falls in community dwelling older people?

Alison Pighills principal research fellow, Avril Drummond professor, Shelley Crossland occupational therapist, David J Torgerson professor

Mackay Institute of Research and Innovation, Queensland Health, Mackay Base Hospital, Queensland 4740; College of Healthcare Sciences, James Cook University, Townsville, Queensland, Australia; School of Health Sciences, University of Nottingham, Nottingham, UK; Mental Health Services for Older People, Leicestershire Partnership NHS Trust, Leicester, UK; York Trials Unit, Department of Health Sciences, University of York, York, UK

What you need to know

• Evidence suggests that environmental interventions can prevent falls in older people at high risk of falls, but they have little or no benefit in people at low risk
• Offer environmental assessment and modification led by an occupational therapist to people over 65 who have had a fall in the past year, use a mobility aid, need assistance with any activities of daily living, take psychoactive medications, or are concerned about falling
• Environmental assessment and modification encompasses a comprehensive, validated functional assessment of the individual in their home environment, a joint problem solving approach, and follow-up as required

One third of people over the age of 65 experience a fall.1 The health and social care costs of falls are increasing with longevity.1–3 Falls are one of the leading causes of morbidity and death caused by injury in people over 75. Nearly a quarter of older people who fall are concerned about further falls, and some restrict activity. This can result in physical deconditioning, increased risk of future falls, institutionalisation, and reduced quality of life.4

Box 1 lists features that predispose older people to falls.3

We categorise falls risk as

High falls risk—≥65 years, have a history of falls, and also possess one or more of the other risk factors for falls
Moderate risk of falls—≥65 years and possess one of the above additional risk factors
Low falls risk—Possess only one falls risk factor

Risk factors for falls can be categorised as

• Intrinsic (personal risk factors such as age and gender)
• Extrinsic (environmental risk factors/environmental hazards)
• Behavioural (activity related risk factors).6,7

Environmental hazards, such as trailing cables and poor lighting, are linked to 30-50% of falls in observational studies.1,8 Guidelines in Australia,9 the US,10 and Britain11 recommend interventions to reduce environmental hazards for older people at risk of falling. However, it remains uncertain whether environmental assessment and modification reduces falls in high risk older people, and which healthcare workers most effectively provide this intervention.

Box 2 gives examples of environmental interventions. Such interventions are typically provided by occupational therapists.
who specialise in environmental assessment and modification. However, in research studies, environmental interventions have been provided by healthcare support workers and healthcare professionals such as nurses and physiotherapists. The intensity of environmental assessment and modification ranges from hazard screening checklists, administered without the older person necessarily being present, to high intensity intervention comprising a comprehensive functional assessment of the older person in their home environment. Thus, the level of expertise of the healthcare worker and the intensity of the environmental intervention are likely to influence the outcome.

What is the evidence of uncertainty?

Search strategy

We searched the Cochrane Database of Systematic Reviews, Medline, Embase, and CINAHL (Cumulative Index to Nursing and Allied Health Literature) for studies published between 2010 and 2017. We applied English language and peer-reviewed journal restrictions. We used the following terms for the literature search:

"accidental falls", "fall", "fall elderly", "aged", "older", "elder", "senior", "home N3 assessment or intervention or design or hazard or modification or safety", "home N3 hazard N3 reduction N3 visit", "assessment or design or hazard or modification or safety or risk", "facility design and construction"

We found four systematic reviews of trials on environmental assessment and modification in community dwelling older people, including a Cochrane Review which included eight randomised controlled trials isolating the clinical effectiveness of environmental assessment and modification, and four clinical guidelines. Best evidence suggests a possible benefit of high intensity guidelines. However, in research studies, environmental interventions have been provided by healthcare support workers and healthcare professionals such as nurses and physiotherapists. The intensity of environmental assessment and modification ranges from hazard screening checklists, administered without the older person necessarily being present, to high intensity intervention comprising a comprehensive functional assessment of the older person in their home environment. Thus, the level of expertise of the healthcare worker and the intensity of the environmental intervention are likely to influence the outcome.

Is ongoing research likely to provide relevant evidence?

We searched the Cochrane Database of Systematic Reviews, ClinicalTrials.gov, the World Health Organization, and Australian New Zealand Clinical Trials Registry for research protocols on environmental assessment and modification; environmental interventions; occupational therapy; falls prevention; and community dwelling older people. Ongoing research is likely to add to the evidence on the clinical effectiveness of environmental interventions delivered by occupational therapists for falls prevention. The question of whether trained home care support workers and other professionals can deliver environmental assessment and modification still needs to be addressed.

We found two ongoing studies: a small study (15 participants) in Chicago investigating an occupational therapist led falls prevention intervention to reduce fear of falling, and the Occupational Therapy Intervention Study (OTIS) which we are conducting. The OTIS trial aims to evaluate effectiveness of occupational therapist led environmental assessment and modification delivered to older people at moderate to high risk of falls. To date, 1331 older people have been randomised to high intensity environmental assessment and modification or usual care control. The trial is in the follow-up phase, in which fall events are being recorded over one year. Follow-up is scheduled to be completed in late 2019. This trial will add to the evidence base on whether occupational therapist led environmental assessment and modification delivered to people at moderate to high risk is clinically effective in preventing falls. This appears pragmatic given the lack of evidence on benefit in moderate or low risk people, and considering the cost and resource implications of occupational therapists intervening with people in all risk categories.

What should we do in the light of the uncertainty?

We recommend that occupational therapist led environmental assessment and modification is clinically effective compared with usual care controls. This appears pragmatic given the lack of evidence on benefit in moderate or low risk people, and considering the cost and resource implications of occupational therapists intervening with people in all risk categories.
research. This could be due to a perceived lack of robust evidence, limited awareness of clinical guidelines, complexity of the intervention, and a perceived lack of practitioner skill and time to carry out the assessment.

When referring older people at high risk of falls for occupational therapy intervention, explain to your patient that the occupational therapist will support them to identify hazards in the home and those activities which might increase the risk of falling, and that the therapist and patient will jointly consider solutions. Active engagement of older people in environmental interventions is vital. The context, environment, use of environment, and a person’s capacity are key features of occupational assessment and modification to reduce falls risk.

Occupational therapy practice aims to enhance, restore, or create environments and a person

Education into practice

- How would you assess whether an older person is at high risk of falls?
- What would you include in a comprehensive environmental assessment, who would provide it, and which patients would you offer it to?
- Of the frail older patients that you treated in the last year following a fall, how many received an environmental assessment and functional assessment in their home with follow-up?

How patients were involved in the creation of this article

A member of the OTIS Consumer Reference Group reviewed the manuscript and provided feedback. We thank her for her input. As a result, we changed the article in the following ways:

- We clarified the term “community dwelling”
- We specified that only some, not all, of those who are fearful of falling subsequently restrict their activity
- We provided more information on factors causing escalation in the cost of falls

What patients need to know

- If you are 65 or over and live in the community, your risk of falls in the future is high if you have had a fall in the past year, use a mobility aid, need assistance with any activities of daily living, take psychotropic medications, or are concerned about falling
- It is likely that environmental assessment and modification, provided by an occupational therapist, would reduce your risk of future falls
- An occupational therapist visits your home to assess and recommend modifications to the environment and tasks that you perform. This may reduce falls hazards and improve your independence and/or safety.
- The therapist would also consider whether assistive technology might help to maintain or improve your independence
- Occupational therapists typically ask you to identify what you think puts you at risk of falling and you jointly problem solve and agree on solutions.
